

Normal characterises DVR

Let A be a 1-dim Noetherian local integral domain

Then A is normal if and only if A is a DVR.

Note: 1-dim local integral domain

$\Leftrightarrow A$ has exactly 2 prime ideals \emptyset in \mathfrak{m} .

Normal = A is integrally closed in $K = \text{Frac } A$.

Step 1. 1-dim Noetherian integral domain.

For any nonzero x in \mathfrak{m} , there exists y in A , $y \notin (x)$ such that $\mathfrak{m} = \{ z \in A \mid z*y \in (x) \}$.

Consider the module $A/(x)$. Any nonzero \bar{y} in $A/(x)$, has an annihilator ideal $\text{Ann } \bar{y}$. In terms of a representative y in A this means that y is not in (x) , and Ann is the ideal of A

$\text{Ann } \bar{y} = \{ z \in A \mid z*y \in (x) \}$.

If $\text{Ann } \bar{y}$ is maximal among all the ideals $\text{Ann } \bar{y}$ then it is prime. Given 1-dim local, the only possibility is $\text{Ann } \bar{y} = \mathfrak{m}$.

Work with y in A . Suppose $z_1, z_2 \notin \text{Ann } \bar{y}$. Then $z_2*y \notin (x)$, so that $\text{Ann } (z_2*\bar{y})$ contains $\text{Ann } \bar{y}$, and the maximal assumption implies they are equal. Then $z_1 \notin \text{Ann } \bar{y}$ implies $z_1*z_2*y \notin (x)$, and also the product $z_1*z_2 \notin (x)$. Therefore the ideal $\text{Ann } \bar{y}$ is prime.

Note: The submodule $A.\bar{y}$ in $A/(x)$ is then isomorphic to the residue field A/\mathfrak{m} . This means that \mathfrak{m} is an associated prime of $A/(x)$, so that the result is part of primary decomposition: quite generally any finite module M has a Jordan-Holder sequence with successive quotients of the form A/P with P a in $\text{Spec } A$ an associated prime of M .

[Step 1 did not use integrally closed.]

Step 2. If x, y as in Step 1, then element y/x in $\text{Frac } A$ is not in A , but $\mathfrak{m}(y/x)$ in A . Therefore, dichotomy: either

(I) $(y/x)*\mathfrak{m} \subset \mathfrak{m}$. This implies that y/x is integral over A by the determinant trick. This is impossible if A is integral, because y/x in A , contradicting $y \notin (x)$.

(II) $(y/x)m = A$. This implies there exists some t in m such that $t = x/y$. Then $m = (t)$ is principal: in fact for z in m , $(y/x)z$ in A , so that $z = t((y/x)z)$ in (t) .
